## Abstract:

**Pneumonia is contamination that stimulates the air sacs in one or both lungs[1]. The air sacs may fill with watery substance or suppuration (purulent substance), causing cough with phlegm or pus, fever, chills, and difficulty breathing[2]. A variety of life form, including bacteria, viruses, and fungi, can cause pneumonia. Pneumonia can range in graveness from mild to life-threatening[1]. It is most consequential for infants and young children, people older than age 65, and people with health problems or weakened immune systems[2]. The author has applied a convolution neural network approach and achieved the accuracy of 88 % on training datasets whereas transfer learning(Inception V3) approach achieved an accuracy of 97% comprised of approximately 5300 images.**

**Keywords:** Deep Learning, Convolutional Neural Network, Pneumonia.

## 1. Introduction

Pneumonia is an infection that inflames the air sacs in one or both lungs[1]. The signs and symptoms of pneumonia vary from mild to severe, depending on factors such as the type of germ causing the infection, and your age and overall health. Mild signs and symptoms often are similar to those of a cold or flu, but they last longer. Newborns and infants may not show any sign of the infection[1]. Or they may vomit, have a fever and cough, appear restless or tired and without energy, or have difficulty breathing and eating. Many germs can cause pneumonia. The most common are bacteria and viruses in the air we breathe. Your body usually prevents these germs

from infecting your lungs. But sometimes these germs can overpower your immune system, even if your health is generally good[2]. Pneumonia can affect anyone. But the two age groups at highest risk are:

1. Children who are 2 years old or younger[1]
2. People who are age 65 or older

To help prevent pneumonia:

**Get vaccinated.** Vaccines are available to prevent some types of pneumonia and the flu. Talk with your doctor about getting these shots. The vaccination guidelines have changed over time so make sure to review your vaccination status with your doctor even if you recall previously receiving a pneumonia vaccine[1].

**Make sure kid get vaccinated.** Doctors advocate a different pneumonia vaccine for teenager younger than age 2 and for children ages 2 to 5 years who are at particular risk of pneumococcal disease. Children who attend a group childcare center should also get the vaccine. Doctors also recommend flu shots for children older than 6 months[1].

**Practice good hygiene.** To protect yourself against respiratory infections that sometimes lead to pneumonia, wash your hands regularly or use an alcohol-based hand sanitizer[1].

**Don't smoke.** Smoking damages your lungs' natural defenses against respiratory infections[2].

**Keep your immune system strong.** Get enough sleep, exercise regularly and eat a healthy diet.

## 2. APPROACH AND IMPLEMENTATION

This paper uses Python 3, Keras and TensorFlow in the backend to write the program for implementing the proposed approach[5]. TensorFlow is an open-source framework created by Google for performing deep learning and the weights of INCEPTION V3 were downloaded and used[4]. The authors have trained the computer to recognize

images and classify them into one category. The authors have used dropouts to reduce overfitting and data augmentation technique to make up for any datasets which are not present.

The results shown in this section are graphs obtained after the training and validation have been completed. In a neural network built from scratch, there is a gradual increase in accuracy, whereas in transfer learning, there is a step rise in the accuracy.

folders named NORMAL and PNEUMONIA which are used to train the convolutional neural network. Similarly, for validation and testing of images

The results shown in this section are graphs obtained after the training and validation have been completed. In a neural network built from scratch, there is a gradual increase in accuracy, whereas in transfer learning, there is a step rise in the accuracy.

## 3. RESULTS

The experiment was carried out on a well-conditioned dataset for validation and test for any immanent bias in the datasets.

## 2. image of neural network

## 3. Image of visualization of Transfer learning

## 4. CONCLUSION

To conclude, the accuracy of 88% was achieved on fairly large datasets but the presence of fewer

validation data the accuracy of validation data sets was not so good. the accuracy on test datasets, however, was very good on 600 images datasets the highest accuracy achieved for NORMAL chest Xray was 80% and for pneumonia was 92%. whereas for transfer learning approach the accuracy highly increased train accuracy of 97% and test accuracy of 95%. so it can be concluded that transfer learning approach was much better than simple CNNs.
